Aux. 1ra: Dr. Juan I. Manassaldi

Equipos con reacción química

Un sistema general de N reacciones, en las que intervienen NC componentes puede representarse como:

$$\sum_{i=1}^{NC} a_{ij} A_i = 0 \quad j = R1, R2, \dots, RN$$

Donde:

A_i : fórmula molecular de la especie i

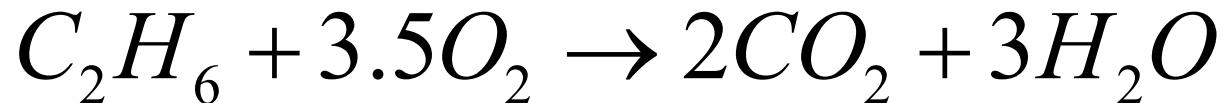

a_{ij} : coeficiente estequiométrico de la especie “i” en la reacción “j”

$a_{ij} < 0$: La especie “i” es un reactivo de la reacción “j”

$a_{ij} > 0$: La especie “i” es un producto de la reacción “j”

$a_{ij} = 0$: La especie “i” no interviene en la reacción “j”

Equipos con reacción química

$$\sum_{i=1}^{NC} a_{ij} A_i = 0 \quad j = R1, R2, \dots, RN$$

$$a_{CH_4,R1} = -1 \quad a_{O_2,R1} = -2 \quad a_{CO_2,R1} = 1 \quad a_{H_2O,R1} = 2 \quad a_{C_2H_6,R1} = 0$$

$$a_{CH_4,R2} = 0 \quad a_{O_2,R2} = -3.5 \quad a_{CO_2,R2} = 2 \quad a_{H_2O,R2} = 3 \quad a_{C_2H_6,R2} = -1$$

Equipos con reacción química

Para cada una de las N reacciones:

$$r_j \left[\frac{1}{volumen \times tiempo} \right] \begin{array}{l} \text{Velocidad de avance de la reacción "j".} \\ \text{Siempre} > 0 \end{array}$$

$$r_{ij} \left[\frac{moles\ de\ i}{volumen \times tiempo} \right] \text{Generación de la especie "i" por unidad de volumen y unidad de tiempo, causada exclusivamente por el avance de la reacción "j"}$$

$$r_j = \frac{r_{ij}}{a_{ij}} \rightarrow r_j = \frac{r_{1j}}{a_{1j}} = \frac{r_{2j}}{a_{2j}} = \dots = \frac{r_{NCj}}{a_{NCj}}$$

$$r_{ij} = a_{ij} \times r_j \quad \forall i, j$$

Equipos con reacción química

Para cada uno de los NC componente:

$$r_i = \sum_{j=R1}^{RN} r_{ij} = \sum_{j=R1}^{RN} a_{ij} \times r_j$$

$$r_i \left[\frac{\text{moles de } i}{\text{volumen} \times \text{tiempo}} \right]$$

Generación neta de la especie “i” por unidad de volumen y unidad de tiempo, causada por el conjunto de N reacciones

Equipos con reacción química

Se pueden definir velocidades netas independientes del volumen del reactor:

$$R_j \left[\frac{1}{\text{tiempo}} \right] \quad \begin{array}{l} \text{Velocidad de avance de la reacción "j".} \\ \text{Siempre} > 0 \end{array}$$

$$R_{ij} \left[\frac{\text{moles de } i}{\text{tiempo}} \right] \quad \begin{array}{l} \text{Generación de la especie "i" por unidad de} \\ \text{tiempo, causada exclusivamente por el avance de} \\ \text{la reacción "j"} \end{array}$$

$$R_i \left[\frac{\text{moles de } i}{\text{tiempo}} \right] \quad \begin{array}{l} \text{Generación neta de la especie "i" por unidad de} \\ \text{tiempo, causada por el conjunto de NR reacciones} \end{array}$$

$$R_j = \frac{R_{1j}}{a_{1j}} = \frac{R_{2j}}{a_{2j}} = \dots = \frac{R_{Nj}}{a_{Nj}} \quad R_i = \sum_{j=R1}^{RN} R_{ij} = \sum_{j=R1}^{RN} a_{ij} \times R_j$$

Reactor de conversión fija

El reactor de conversión fija es un modelo de reactor simplificado para el que se especifica la conversión de una reacción.

Para reacciones paralelas, se especifican las conversiones del componente i para la reacción j, $\zeta_{i,j}$.

Usando esta definición obtenemos para la conversión general del componente i:

$$\sum_{j=R1}^{RN} \zeta_{ij} = \frac{m_{in}x_{in,i} - m_{out}x_{out,i}}{m_{in}x_{in,i}}$$

Solo se puede definir para compuesto que ingresan al reactor

Entonces, la generación de la especie "i" por unidad de tiempo debido a la reacción j corresponde a:

$$R_{ij} = -\zeta_{ij} m_{in} x_{in,i} \Rightarrow R_j = -\frac{\zeta_{ij}}{a_{ij}} m_{in} x_{in,i}$$

Cuidado inconsistencias al definir las conversiones

Reactor de conversión fija

Se debe definir la conversión de un solo compuesto por reacción y se lo denomina componente base.

Como se mencionó anteriormente, se cumple la siguiente igualdad para cada reacción:

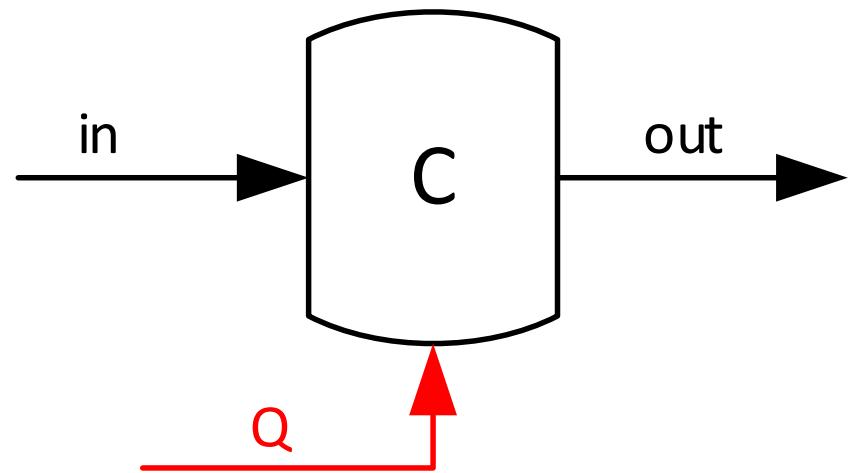

$$R_i = \sum_{j=R1}^{RN} R_{ij} = \sum_{j=R1}^{RN} a_{ij} \times R_j$$

Si i^* es el componente base de la reacción j :

$$R_j = -\frac{\zeta_{i^* j}}{a_{i^* j}} m_{in} x_{in, i^*}$$

$$R_i = \sum_{j=1}^{NR} -a_{ij} \frac{\zeta_{i^* j}}{a_{i^* j}} m_{in} x_{in, i^*} \quad \forall i$$

Reactor de conversión fija

Hipótesis:

- Estado estacionario.
- Se conoce la estequiometría de cada una de las reacciones.
- Se conoce la conversión de un componente por reacción.
- Medio de reacción homogéneo.
- Las entalpías son calculadas tomando como base el calor de formación de cada componente (caso contrario el calor de reacción aparecería en el balance de energía).
- Se toma como positivo el calor que ingresa.

Reactor de conversión fija

$$m_{in}x_{in,i} + R_i - m_{out}x_{out,i} = 0 \quad \forall i$$

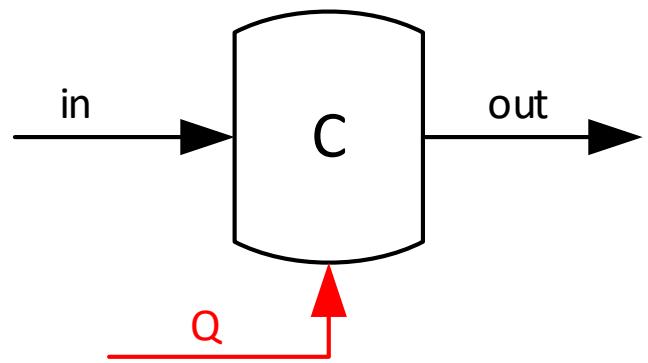

$$R_i = \sum_{j=1}^{NR} -a_{ij} \frac{\zeta_{i^*j}}{a_{i^*j}} m_{in}x_{in,i^*} \quad \forall i$$

$$\sum_{i=1}^{NC} x_{in,i} = 1 \quad \sum_{i=1}^{NC} x_{out,i} = 1$$

$$m_{in}H_{in} + Q - m_{out}H_{out} = 0$$

Las entalpías deben incluir el calor de formación!

$$f(T_{in}, P_{in}, H_{in}, x_{in}) = 0 \quad f(T_{out}, P_{out}, H_{out}, x_{out}) = 0$$

Reactor de conversión fija

$$m_{in}x_{in,i} + R_i - m_{out}x_{out,i} = 0 \quad \forall i \quad \text{NC}$$

$$R_i = \sum_{j=1}^{NR} -a_{ij} \frac{\zeta_{i^*j}}{a_{i^*j}} m_{in}x_{in,i^*} \quad \forall i \quad \text{NC}$$

$$\sum_{i=1}^{NC} x_{in,i} = 1 \quad \sum_{i=1}^{NC} x_{out,i} = 1 \quad \text{2}$$

$$m_{in}H_{in} + Q - m_{out}H_{out} = 0 \quad \text{1}$$

$$f(T_{in}, P_{in}, H_{in}, x_{in}) = 0 \quad f(T_{out}, P_{out}, H_{out}, x_{out}) = 0 \quad \text{2}$$

GL =2

$$f(T_{out}, P_{out}, H_{out}, x_{out}) = 0$$

Reactor de conversión fija (adiabático o calor dado)

Calculamos generación neta de cada componente.

¡Cuidado! Tienen alcanzan los reactivos sino se obtendrán valores negativos de composición.

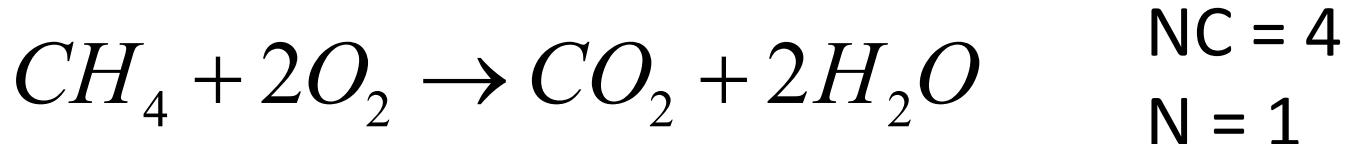

Resolvemos el balance de Materia con reacción química.

$$H_{out} = \frac{m_{in} H_{in}}{m_{out}} \rightarrow \text{Si conocemos } Q: H_{out} = \frac{m_{in} H_{in} + Q}{m_{out}}$$

$$f(T_{out}, P_{out}, H_{out}, x_{out}) = 0 \rightarrow T_{out}$$

¡Cuidado!
Debemos conocer o encontrar
la/s fase/s

Ejemplo: Combustión de metano con aire

Asumimos al metano como componente base de la reacción y suponemos una conversión del 100%.

$$m_{in} = 100 \text{ mol} \cdot \text{seg}^{-1}$$

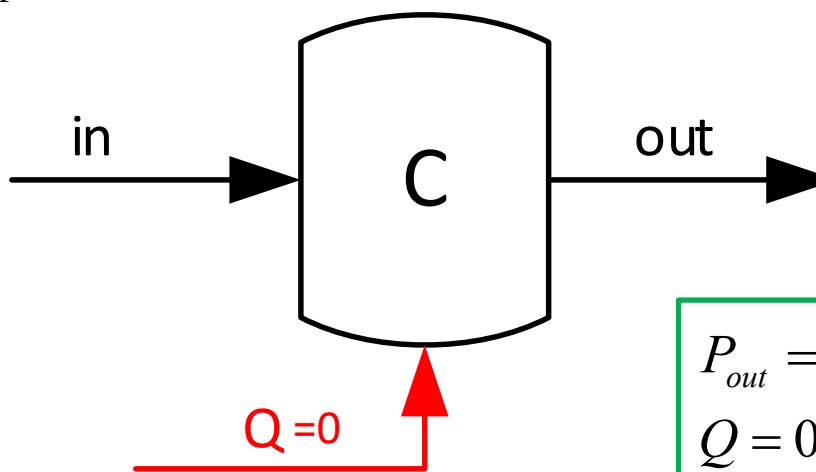

$$x_{in,CH_4} = 0.038$$

$$x_{in,O_2} = 0.202$$

$$x_{in,N_2} = 0.760$$

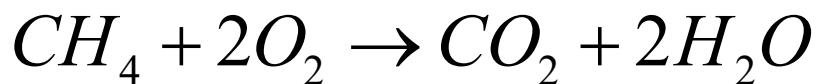

$$T_{in} = 473.15 K$$

$$P_{in} = 4 \text{ bar}$$

$$P_{out} = 4 \text{ bar} \\ Q = 0$$

Combustión de metano con aire (Rx)

$$\begin{array}{lll} a_{CH_4} = -1 & a_{CO_2} = 1 & a_{N_2} = 0 \\ a_{O_2} = -2 & a_{H_2O} = 2 & \zeta_{CH_4} = 1 \end{array}$$

$$R_i = \sum_{j=1}^{NR} -a_{ij} \frac{\zeta_{i^*j}}{a_{i^*j}} m_{in} x_{in,i^*} \rightarrow R_i = -a_i \frac{\zeta_{CH_4}}{a_{CH_4}} m_{in} x_{in,CH_4}$$

$$R_{CH_4} = -(-1) \frac{1}{(-1)} 100 \times 0.038 = -3.8 \quad R_{H_2O} = -(2) \frac{1}{(-1)} 100 \times 0.038 = 7.6$$

$$R_{O_2} = -(-2) \frac{1}{(-1)} 100 \times 0.038 = -7.6 \quad R_{N_2} = -(0) \frac{1}{(-1)} 100 \times 0.038 = 0$$

$$R_{CO_2} = -(1) \frac{1}{(-1)} 100 \times 0.038 = 3.8$$

Combustión de metano con aire (BMxC)

$$m_{in}x_{in,i} + R_i - m_{out}x_{out,i} = 0 \quad \forall i$$

↓

$$3.8 - 3.8 - m_{out}x_{out,CH_4} = 0$$

$$20.2 - 7.6 - m_{out}x_{out,O_2} = 0$$

$$76 + 0 - m_{out}x_{out,N_2} = 0$$

$$0 + 3.8 - m_{out}x_{out,CO_2} = 0$$

$$0 + 7.6 - m_{out}x_{out,H_2O} = 0$$

$$x_{out,CH_4} + x_{out,O_2} + x_{out,N_2} + x_{out,CO_2} + x_{out,H_2O} = 1$$

$$\rightarrow \begin{cases} m_{out} = 100 \\ x_{out,CH_4} = 0 \\ x_{out,O_2} = 0.126 \\ x_{out,N_2} = 0.76 \\ x_{out,CO_2} = 0.038 \\ x_{out,H_2O} = 0.076 \end{cases}$$

Combustión de metano con aire (BE)

$$H_{out} = \frac{m_{in} H_{in}}{m_{out}}$$

$$H_{out} = \frac{100 \times 2388.645}{100}$$

$$H_{out} = 2388.645 \frac{J}{mol}$$

De la librería Raoult Law

$$x_{out,CH_4} = 0$$

$$x_{out,O_2} = 0.126$$

$$x_{out,N_2} = 0.76$$

$$x_{out,CO_2} = 0.038$$

$$x_{out,H_2O} = 0.076$$

$$f(T_{out}, P_{out}, H_{out}, x_{out}) = 0 \rightarrow T_{out} = 1380.92 K$$

Fase gaseosa

$P_{out} = 4 \text{ bar}$

Reactor de conversión fija (flujos x componentes)

$$m_{in,i} + R_i - m_{out,i} = 0 \quad \forall i$$

$$R_i = \sum_{j=R1}^{RN} -a_{ij} \frac{\zeta_{i^*j}}{a_{i^*j}} m_{in,i^*} \quad \forall i$$

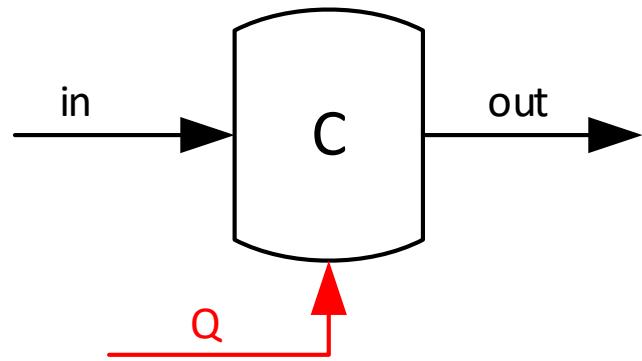

$$m_{in} = \sum_{i=1}^{NC} m_{in,i} \quad m_{out} = \sum_{i=1}^{NC} m_{out,i}$$

$$m_{in,i} = m_{in} x_{in,i} \quad \forall i$$

$$m_{out,i} = m_{out} x_{out,i} \quad \forall i$$

$$m_{in} H_{in} + Q - m_{out} H_{out} = 0$$

$$f(T_{in}, P_{in}, H_{in}, x_{in}) = 0 \quad f(T_{out}, P_{out}, H_{out}, x_{out}) = 0$$

$$\begin{array}{cccccc} m_{in} & m_{in,i} & x_{in,i} & \zeta_{i^*j} \\ m_{out} & m_{out,i} & x_{out,i} & \\ H_{in} & T_{in} & P_{in} & H_{out} & T_{out} & P_{out} \end{array}$$

$$Q \quad R_i$$

Reactor de conversión fija (flujos x componentes - MS)

$$m_{in,i} + R_i - m_{out,i} = 0 \quad \forall i \quad 1$$

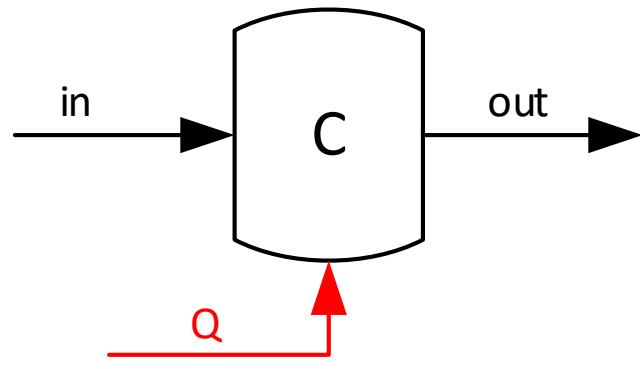

$$R_i = \sum_{j=R1}^{RN} -a_{ij} \frac{\zeta_{i^*j}}{a_{i^*j}} m_{in,i^*} \quad \forall i \quad 2$$

Q

CSTR (Continuously Stirred Tank Reactor)

El CSTR (Reactor de tanque continuamente agitado o mezcla completa) es un modelo de reactor simplificado en el que se supone que el contenido del reactor es de única fase y está bien mezclado.

- Los balances de materia y energía se plantean suponiendo un medio de reacción completamente homogéneo.
- Se tiene en cuenta las características geométricas del reactor.
- Se consideran las expresiones de velocidad de reacción.

CSTR (Continuously Stirred Tank Reactor)

Como ahora consideramos el volumen del reactor, utilizamos la velocidad de avance de la reacción por unidad de volumen previamente presentadas.

$$r_j \left[\frac{1}{\text{volumen} \times \text{tiempo}} \right] \quad r_{ij} \left[\frac{\text{moles de } i}{\text{volumen} \times \text{tiempo}} \right]$$

$$r_j = \frac{r_{ij}}{a_{ij}} \rightarrow r_j = \frac{r_{1j}}{a_{1j}} = \frac{r_{2j}}{a_{2j}} = \dots = \frac{r_{NCj}}{a_{NCj}}$$

$$r_i = \sum_{j=R1}^{RN} r_{ij} = \sum_{j=R1}^{RN} a_{ij} \times r_j \quad r_i \left[\frac{\text{moles de } i}{\text{volumen} \times \text{tiempo}} \right]$$

CSTR (Continuously Stirred Tank Reactor)

Las velocidades de reacción **por lo general** vienen expresadas como funciones de la temperatura y concentraciones molares de las especies interviniéntes:

$$r_j = f_j(T, C_1, C_2, \dots, C_{NC}) \quad \forall j$$

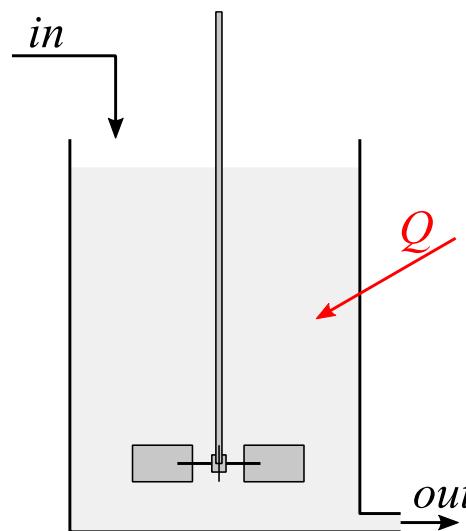

Una forma mas generalizada de expresar la velocidad de reacción es:

$$r_j = k_j(T) \prod_{i=1}^{NC} [A_i]^{\alpha_{ij}} \quad \forall j$$

Donde $[A_i]$ se denomina base y α_{ij} orden.

Las bases mas frecuentes son: Concentración, presión parcial, actividad, fugacidad, etc.

CSTR (Continuously Stirred Tank Reactor)

Hipótesis:

- Se conoce la estequiométría de cada una de las reacciones
- Se conocen las expresiones de velocidad de reacción (r_j)
- Estado estacionario
- Medio de reacción homogéneo
- Las entalpías están calculadas tomando como base el calor de formación de cada componente.
- Se considera que el medio de reacción intercambia calor con una corriente energética.

Ejemplo: Reactor CSTR refrigerado

$$r_D = k_D \times C_A$$

$$r_I = k_I \times C_B \times C_C$$

$$r_A = -k_D C_A + k_I C_B C_C$$

$$r_B = k_D C_A - k_I C_B C_C$$

$$r_C = k_D C_A - k_I C_B C_C$$

Ejemplo

Hipótesis:

- Reacción reversible exotérmica en fase homogénea.
- Reactor Mezcla completa.
- Camisa de refrigeración mezcla completa.
- Los coeficientes cinéticos son conocidos ya que son función de la temperatura (funcional tipo Arrhenius).
- Evaporación del líquido despreciable.
- UA es dato
- Tanque cilíndrico de área A_T .
- Caída de presión a través de la camisa nula
- Fluido de la camisa compuesto puro.

Reactor CSTR

$$m_{in,i} + r_i V - m_i = 0 \quad i = A, B, C$$

$$r_A = -k_D C_A + k_I C_B C_C \quad r_B = k_D C_A - k_I C_B C_C \quad r_C = k_D C_A - k_I C_B C_C$$

$$m_{in,i} = m_{in} x_{in,i} \quad i = A, B, C \quad m_i = m x_i \quad i = A, B, C$$

$$C_i = \rho x_i \quad \forall i$$

$$m_{in} = \sum_{i=1}^{NC} m_{in,i} \quad m = \sum_{i=1}^{NC} m_i$$

La reacción es exotérmica, buscamos que el calor sea positivo

$$m_{in} H_{in} - Q - mH = 0$$

$$f(T, P, H, x) = 0$$

$$f(T, P, \rho, x) = 0$$

$$k_D = A_D e^{\frac{-E_D}{RT}} \quad k_I = A_D e^{\frac{-E_I}{RT}}$$

$$f(T_{in}, P_{in}, H_{in}, x_{in}) = 0$$

Utilizamos el calor de formación como entalpia de de referencia

Reactor CSTR (MS)

$$m_{in,i} + r_i V - m_i = 0 \quad i = A, B, C$$

$$r_A = -k_D C_A + k_I C_B C_C \quad r_B = k_D C_A - k_I C_B C_C \quad r_C = k_D C_A - k_I C_B C_C$$

$$m_i = m x_i \quad i = A, B, C$$

$$C_i = \rho x_i \quad \forall i$$

$$m = \sum_{i=1}^{NC} m_i$$

$$m_{in} H_{in} - Q - mH = 0$$

$$f(T, P, H, x) = 0$$

$$f(T, P, \rho, x) = 0 \quad k_D = A_D e^{\frac{-E_D}{RT}} \quad k_I = A_I e^{\frac{-E_I}{RT}}$$

Reactor CSTR refrigerado (Estrategia de resolución)

Propongo: T^*

Resuelvo el reactor CSTR isotérmico a la temperatura propuesta.

Calculamos la temperatura de salida de la camisa:

$$H_2 = \frac{m_1 H_1 + Q^*}{m_2} \quad f(T_2, P_2, H_2) = 0 \rightarrow T_2$$

Chequemos la ecuación de transferencia de calor:

$$\Delta t_c = T^* - T_2$$

$$Q = UA\Delta t_c$$

$$Q = Q^* ? \begin{cases} \text{si : Terminamos} \\ \text{no : Proponemos } T^* = \frac{Q^*}{(UA)} + T_2 \end{cases}$$
